Note :

The result is Reactive/ positive. This has been confirmed by three different assay methods, in accordance with the National HIV testing guidelines recommended by NACO.

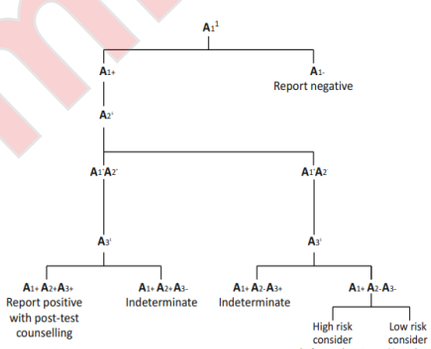

Clinical Significance :

- This is a screening test. Any positive or non-correlating result needs to be confirmed with a confirmatory test, such as Western Blot or HIV RNA PCR testing etc.
- All results should be interpreted in conjunction with the patient's clinical history and other findings.
- HIV reporting follows Strategy 3 of the National Guidelines of HIV Testing by NACO (National AIDS Control Organization), utilizing highly sensitive and specific assays.
- All indeterminate results require retesting with a fresh sample after 14-28 days or confirmation by a confirmatory test.
- Indeterminate cases are reported if one or two of the three assays report reactive results.

Limitations :

- Several conditions can lead to false positive or false negative results.
- Common causes of a false positive result include autoimmune diseases, alcoholic hepatitis, primary biliary cirrhosis, leprosy, multiple pregnancies, and cross-reactive antibodies.
- Common causes of a false negative result include testing during the window period or the end stage of the disease.

FINAL RESULT INTERPRETATION : As per the below Strategy 3 flow diagram of HIV Testing by NACO guidelines.
